1 Intro

Theorem 1.0.1. *radical ideal is generated by a polynomial f with no multiple roots.*

Suppose $J \subset \mathbb{C}[x_1, \dots, x_n]$ is an ideal. Then $I(Z(J)) = \text{rad}(J) = \{f \mid f^n \in J\}$

Definition 1.0.2. *radical ideal is generated by a polynomial f with no multiple roots. cokernel: take the image of f and mod out by image of f .*

1.1 Modules

Let R be a commutative ring. An R -module M is an abelian group $(+)$ with a map $R \times M \rightarrow M$ written $(r, m) \mapsto rm$. Satisfying

1. associativity: $r(sm) = (rs)m$ for all $r, s \in R, m \in M$.

2. distributivity: $r(m + m') = rm + rm'$ and $(r + r')m = rm + r'm$ for all $r, r' \in R, m, m' \in M$.
3. unitality: $1m = m$ for all $m \in M$.

Several things you could derive from the definition: $0m = 0, (-1)m = -m$, etc.

Example 1.1.1. Let $R = k[x]$. A $k[x]$ -module is

- a k -vector space M
- with a map $xM \rightarrow M$, where $m \mapsto xm$, a k linear transformation.

Example 1.1.2. What is an R -submodule of R ? It's

1. $J \subseteq R$;
2. closed under addition, 0, negatives;
3. for any $r \in R, j \in J, rj \in J$.

an ideal.

Definition 1.1.3. Let M be an R -module, N a subgroup of M . N is a *submodule* if for any $n \in N$ and $r \in R$, the product rn is in N .

Definition 1.1.4. If M is an R -module, we shall write $\text{ann } M$ for the annihilator of M ; that is,

$$\text{ann } M = \{r \in R \mid rM = 0\},$$

which is an ideal.

Definition 1.1.5. Let $I \subseteq R$ an ideal, M an R -module. We denote

$$IM = \left\{ \sum a_i m_i \mid a_i \in I, m_i \in M \right\} \subseteq M$$

the smallest R -submodule of M containing all elements of the form am , where $a \in I, m \in M$.

Example 1.1.6. Suppose M is an R -module. For $N, N' \subseteq M$ submodules,

$$[N : N'] \subseteq R \quad x \in [N : N'] \iff xN' \subseteq N.$$

For N a submodule, I an ideal

$$[N : I] \subseteq M. \quad y \in [N : I] \iff Iy \subseteq N.$$

The point of having the above is to generalize the annihilator.

Example 1.1.7. $\text{ann } M = [0 : M]$.

Some operations we could do. Given a sequence of modules M_1, M_2, \dots

Definition 1.1.8. We denote

$$\prod_{i \in I} M_i = \{(m_1, m_2, \dots) \mid m_i \in M_i\}.$$

$\prod M_i$ is an R -module with componentwise addition and scalar multiplication.

Note that $\oplus M_i \subseteq \prod M_i$, a sub- R -module.

Also, $\oplus M_i = \{(m_i)_{i \in I} \mid \text{only finitely many } m_i \text{ are zero}\}$

Suppose we have an R -module homomorphism

$$f : M \rightarrow N.$$

We could construct 3 modules: $\ker(f) \subseteq M, \operatorname{Im}(f) \subseteq N, \operatorname{coker}(f) = N/\operatorname{Im}(f)$

Definition 1.1.9. Suppose we have R -module homomorphism

$$f : M \rightarrow N \quad g : N \rightarrow P.$$

This is exact if $\operatorname{Im} f = \ker g$.

Definition 1.1.10. If we have a sequence of maps

$$\cdots \rightarrow M_1 \rightarrow M_2 \rightarrow M_3 \rightarrow \cdots.$$

then we say it's exact iff each 2-term sequence is exact.

Saying $0 \rightarrow M \rightarrow N$ is exact is saying f is injective. And $M \rightarrow N \rightarrow 0$ is exact is saying f is surjective.

Definition 1.1.11. A short exact sequence is an exact sequence

$$0 \rightarrow M \rightarrow N \rightarrow P \rightarrow 0 \quad f : M \rightarrow N, g : N \rightarrow P.$$

This tells us that

1. M iso to $\operatorname{Im}(f)$
2. P iso to $N/\ker(g)$
3. $\ker(g) = \operatorname{Im}(f)$, P iso $\operatorname{coker}(f)$

Definition 1.1.12. A free R -module is an R -module isomorphic to $\oplus_{i \in I} R$. In particular, R^n are the finitely generated free modules.

Definition 1.1.13. A module M is finitely generated if there exists $m_1, \dots, m_n \in M$ such that every element of M is of the form $\sum_{i=1}^n a_i m_i$ for some $a_i \in R$.

Definition 1.1.14. A module M is finitely presented if there exists an exact sequence

$$R^n \rightarrow R^m \rightarrow M \rightarrow 0.$$

2 Localization

2.1 Fractions

Suppose R is a ring, $U \subseteq R$ is a subset that is closed under multiplication, and contains the unit $1 \in R$.

Definition 2.1.1. We can form the localization $R[U^{-1}]$, whose elements are

$$\{(r, s) \mid r \in R, s \in U\}.$$

We also put an equivalence relation on the elements.

$$(r, s) \equiv (r', s') \iff \exists u, v \in U, (ur, us) = (vr', vs').$$

Note that the equivalence relation is different from cross-multiplication as what we do in fractions.

Example 2.1.2. Let $R = \mathbb{Z}, U = \{1, 2, 4, 6, 16, \dots\}$. Then

$$R[U^{-1}] = \mathbb{Z} \left[\frac{1}{2} \right] = \left\{ \frac{p}{q} \mid p \in \mathbb{Z}, q = 2^k \right\}.$$

Definition 2.1.3. In $R[U^{-1}]$, we have a ring.

$$(r, s) + (r', s') = (rs' + r's, ss')$$

$$(r, s) \cdot (r', s') = (rr', ss')$$

$$0 = (0, 1)$$

$$1 = (1, 1)$$

Example 2.1.4. Let $R = \mathbb{Z}/6, U = \{1, 3\}$. Then localization is smaller:

$$R[U^{-1}] = \mathbb{Z}/2.$$

Example 2.1.5. Let $R = \mathbb{C}[x], U = \{1, x, x^2, x^3, \dots\}$. Then

$$R[U^{-1}] = \mathbb{C}[x, x^{-1}] = \{f(x)/x^n \mid f(x) \text{ poly}, n \in \mathbb{N}\} = \left\{ \sum_{n \in \mathbb{Z}} a_n x^n \mid a_n \in \mathbb{C} \right\}.$$

Note that in the summation there should only be finitely many n . The ring is also called Laurent polynomials.

This ring is isomorphic to

$$\mathbb{C}[x, y]/(yx - 1).$$

Note that there is always a ring homomorphism

$$\phi: R \rightarrow R[U^{-1}] \quad \phi(r) = \frac{r}{1}.$$

Example 2.1.6. $R = \mathbb{C}[x_1, \dots, x_n], U = R - \{0\}$. Note U is closed under multiplication because R is an integral domain.

$$R[U^{-1}] = \{f(\vec{x})/g(\vec{x}) \mid f, g \in \mathbb{C}[x_1, \dots, x_n], g \neq 0\}.$$

Proposition 2.1.7. The theory of ideals in $R[U^{-1}]$ is closely related to the theory of ideals in R . Given an ideal J in R , we could have $J \cdot R[U^{-1}]$, which is an ideal in $R[U^{-1}]$.

The map from ideals of $R[U^{-1}]$ to ideals of R is an injection. They are sort of “ideals that don’t meet the set U ”.

An ical J is of the form $\phi^{-1}(L)$ iff for any a, b s.t. $a \in R, b \in U, ab \in J \implies a \in J$.

There is a correspondance between prime ideals of $R[U^{-1}]$ and prime ideals of R that don’t contain any elements of U .

Example 2.1.8. *prime ideals of \mathbb{Q} ; prime ideals of \mathbb{Z} that don’t contain any elements of the set $\{1, 2, 3, 4, 5, \dots\}; \{(0)\}$.*

Definition 2.1.9. Suppose R is a ring. $P \subseteq R$ is a prime ideal. We define R_P to be the localization of the set $U = R - P$.

Note that U is closed under multiplication because P is prime.

Also, R_P has one maximal ideal: PR_P .

There is a correspondance between prime ideals of R_P ; prime ideals of R that don’t contain any elements of U ; prime ideals of R contained in P .

Example 2.1.10.

$$\mathbb{Z}_{(2)} = \left\{ \frac{n}{m} \mid m \text{ odd} \right\}.$$

This has 2 ideals: $(0), (2)$.

Definition 2.1.11. A ring R is *local* if it has a unique maximal ideal.

R_P is always local if P is prime.

If R is a ring, M is an R -module, $U \subseteq R$ is a subset closed under multiplication and 1. We can construct

$$M[U^{-1}] = \left\{ \frac{m}{s} \mid m \in M, s \in U \right\}.$$

$M[U^{-1}]$ is an abelian group and a module on $R[U^{-1}]$.

Example 2.1.12. $R = \mathbb{Z}, U = \{1, 3, 9, 27, \dots\}, M = \mathbb{Z}/10$. Check that $M[U^{-1}] \cong \{0\}$.

2.2 Hom

For R -modules M, N . There is a new R -module $\text{Hom}_R(M, N)$

$$\text{Hom}_R(M, N) \subseteq \{f : M \rightarrow N\}.$$

Functions that are

1. group homomorphisms
2. R -linear: $f(rx) = rf(x)$

Definition 2.2.1. $\text{Hom}_R(M, N)$ is an R -module in the following way.

- $f + g : (f + g)(m) = f(m) + g(m)$

- $rf : (rf)(m) = rf(m)$

There are some properties of Hom .

1. $\text{Hom}_R(R, N) \cong N$, where $f \mapsto f(1), n \in N \mapsto f(r) = rn$. Basically the same as picking an element from N .
- 2.

$$\text{Hom}_R(\oplus_{i \in I} M_i, N) \cong \prod_{i \in I} \text{Hom}_R(M_i, N).$$

The RHS is choosing for each $i \in I$, a homomorphism $M_i \rightarrow N$. There's also

$$\text{Hom}_R(M, \prod_{i \in I} N_i) \cong \prod_{i \in I} \text{Hom}_R(M, N_i).$$

3. If I have R -module homomorphisms

$$\alpha : M \rightarrow M' \quad \beta : N \rightarrow N'.$$

I get a map

$$\text{Hom}_R(\alpha, \beta) : \text{Hom}_R(M', N) \rightarrow \text{Hom}_R(M, N') \quad \text{where} \quad f \mapsto \beta f \alpha.$$

This respects identity functions and function composition. Functorial.

4. Exactness. Hom_R is *left-exact*:

- (a) If $M' \rightarrow M \rightarrow M'' \rightarrow 0$ is an exact sequence, then for any N ,

$$0 \rightarrow \text{Hom}_R(M'', N) \rightarrow \text{Hom}_R(M, N) \rightarrow \text{Hom}_R(M', N)$$

is also exact.

- (b) If $0 \rightarrow N' \rightarrow N \rightarrow N''$ is exact then

$$0 \rightarrow \text{Hom}_R(M, N') \rightarrow \text{Hom}_R(M, N) \rightarrow \text{Hom}_R(M, N'')$$

is exact.

For R -module M, N there is a tensor product $M \otimes_R N$, which we get by taking all formal sums of symbols $m \otimes n, m \in M, n \in N$, mod out by subgroup generated by elements of the form

- $(m + m') \otimes n - m \otimes n - m' \otimes n;$
- $m \otimes (n + n') - m \otimes n - m \otimes n';$
- $(rm) \otimes n - m \otimes (rn).$

Example 2.2.2.

$$R[x_1, \dots, x_n] \otimes_R R[y_1, \dots, y_n] \cong R[x_1, \dots, x_n, y_1, \dots, y_n].$$

Properties of \otimes_R .

- 1.

$$R \otimes_R M \cong M \quad \sum r_i \otimes m_i \mapsto \sum r_i m \quad 1 \otimes m \mapsto m.$$

2.

$$(\oplus M_i) \otimes_R N \cong \oplus (M_i \otimes_R N).$$

3. Functoriality. For R -module homomorphisms $\alpha : M \rightarrow M'$, $\beta : N \rightarrow N'$, we get an R -module homomorphism

$$\alpha \otimes \beta : M \otimes_R N \rightarrow M' \otimes_R N' \quad \sum m_i \otimes n_i \mapsto \sum \alpha(m_i) \otimes \beta(n_i).$$

4. Right exactness. If $M' \rightarrow M \rightarrow M''$ is exact, then

$$M' \otimes_R N \rightarrow M \otimes_R N \rightarrow M'' \otimes_R N \rightarrow 0.$$

is exact.

5. Symmetry.

$$M \otimes_R N \cong N \otimes_R M \quad \sum m_i \otimes n_i \mapsto n_i \otimes m_i.$$

Proposition 2.2.3.

$$M[U^{-1}] \cong R[U^{-1}] \otimes_R M.$$

Proof sketch. The procedure we could do is

$$\frac{m}{u} \mapsto \frac{1}{u} \otimes m \quad \frac{rm}{u} \leftarrow \frac{r}{u} \otimes m.$$

□

Definition 2.2.4. An R -module F is *flat* whenever

$$f : M \rightarrow N \quad \text{is injective,}$$

and the map

$$F \otimes_R M \rightarrow F \otimes_R N \quad \text{is injective.}$$

Alternatively,

$$0 \rightarrow M \rightarrow N \text{ exact} \implies 0 \rightarrow F \otimes_R M \rightarrow F \otimes_R N \text{ exact}.$$

Theorem 2.2.5. $R[U^{-1}]$ is always a flat module over R .

Proof. Suppose $f : M \rightarrow N$ is injective. We need to check $M[U^{-1}] \rightarrow N[U^{-1}]$ is also injective.

Suppose $\frac{m}{u} \in M[U^{-1}]$ which goes to 0 in $N[U^{-1}]$, then $\frac{f(m)}{u} = \frac{0}{1}$ in $N[U^{-1}]$. This means there exists $v \in U$ s.t. $vf(m) = 0$, which leads to $vf(m) = f(vm) = 0$. Since f is injective, $vm = 0$ in M . Then $\frac{m}{u} = \frac{vm}{vu} = \frac{0}{m} = \frac{0}{1}$. □

Example 2.2.6. \mathbb{Q} is a flat module over \mathbb{Z} . $\mathbb{Z}/2$ is a flat module over $\mathbb{Z}/6$. Both $\mathbb{C}(x)$ and $\mathbb{C}[x, x^{-1}]$ are flat over $\mathbb{C}[x]$.

Theorem 2.2.7. A module M over R is zero iff for every maximal ideal m , the localization M_m is zero.

Definition 2.2.8. An R -module M is *Noetherian* if every submodule of M is finitely generated.

Theorem 2.2.9. If

$$0 \rightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \rightarrow 0$$

is exact, then M is Noetherian (resp. Artinian) iff M' and M'' are both Noetherian (resp. Artinian).

2.3 Rings and Modules of Finite Length

Definition 2.3.1. An R -module M is *simple* iff M has exactly 2 R -submodule: 0 and M .

Definition 2.3.2. A *composition series* for a module M is a chain

$$0 = M_0 < M_1 < M_2 < \cdots < M_{n-1} < M_n = M$$

of submodules (with strict inclusion) such that for all $1 \leq i \leq n$, M_i/M_{i-1} is simple.

Proposition 2.3.3. A \mathbb{Z} -module M is simple iff it's of the form \mathbb{Z}/p where p is prime.

Proposition 2.3.4. Let R be an R -module, J be an ideal. R/J is simple iff J is maximal.

Example 2.3.5. Let $R = \mathbb{C}[x, y]$, $M = \mathbb{C}_2[x, y]/(x^2, xy, y^2)$.

Proposition 2.3.6. If k is a field, a compositions series for a vectors space V exists iff V is finite dimensional, the sequence always goes from 0 dimension to 1, 2, and grows to the entire thing V .

Definition 2.3.7. The *length* of an R -module M is the minimal length of a compositions series, if one exists, or ∞ . We denote it as $l(M)$.

Theorem 2.3.8. Every composition series for M has the same length.

Throughout the following, we assume all modules we work with have finite length.

Proposition 2.3.9. If $N < M \implies l(N) < l(M)$.

Proof. Choose a composition series for N :

$$0 < N_1 < N_2 < \cdots < N.$$

We start with a composition series for M of minimal length:

$$0 < M_0 < M_1 < \cdots < M_n = M.$$

We intersect it with N : $N_k = M_k \cap N$. Then we don't necessarily have strict containment.

$$0 = N_0 \leq N_1 \leq N_2 \leq \cdots \leq N_n = N.$$

□

Theorem 2.3.10. *Every composition series of M has the same length.*

Proof. Suppose we have a composition series

$$0 = M_0 < M_1 < \cdots < M_n = M,$$

with the assumption that M_k/M_{k-1} simple. Then

$$0 \leq l(M_0) < l(M_1) < \cdots < l(M_n) = l(M).$$

Thus $n \leq l(M)$. From the definition of length, we know $n = l(M)$. \square

Proposition 2.3.11. $l(M) < \infty$ iff M satisfies ACC and DCC.

Definition 2.3.12. A *finite filtration* of a module M is a sequence

$$0 = M_0 \leq M_1 \leq M_2 \leq \cdots \leq M_n = M.$$

Associated to a filtration, we have *subquotients*

$$M_k/M_{k-1} = \text{gr}^k(M) \quad \text{grading } k.$$

Proposition 2.3.13. Suppose M, N are modules with filtrations $\{M_k\}, \{N_k\}$ and a function $f : M \rightarrow N$ s.t. $f(M_k) \subseteq N_k$. Then we get induced module maps

$$\text{gr}^k(M) \rightarrow \text{gr}^k(N) \quad \text{where} \quad [x] \mapsto [f(x)].$$

Also, if all of these are isomorphisms, then so is f .

Example 2.3.14. $\text{gr}^k(M) \cong 0 \iff M_k/M_{k-1} = 0 \iff M_{k-1} = M_k$.

Theorem 2.3.15 (Snake Lemma). If (DO THE TIKZ)

Proposition 2.3.16. Suppose M has a composition series and N is a submodule with quotient M/N . We have

$$l(M) = l(N) + l(M/N).$$

Suppose M has a filtration, we could take the entire sequence and localize it.

Proposition 2.3.17. If R is Noetherian, then so is any quotient R/J and any localization $S^{-1}R$.

Subrings of Noetherian ring are not necessarily Noetherian.

Theorem 2.3.18. If R is Noetherian, then so is $R[x]$.

Definition 2.3.19. If we have a polynomial $a_0 + a_1x + a_2x^2 + \cdots + a_nx^n, a_n \neq 0, a_i \in R$, we say f has *degree* n and a_n is its *lead coefficient*

Theorem 2.3.20 (Hilbert basis theorem). If R is Noetherian, then so is $R[x]$.

A natural proposition of the theorem will be the following.

Proposition 2.3.21. If R is Noetherian, so is $R[x_1, \dots, x_n]$.

Theorem 2.3.22. If R is Noetherian, so is the power series ring $R[[x]]$.

3 Primary Decomposition

3.1 Associated Primes

Definition 3.1.1. Suppose M is an R -module. The set of *associated primes* is the collection

$$\text{Ass}(M) = \{P \mid P \leq R \text{ is prime } P = \text{ann}(x) \mid x \in M\}.$$

Proposition 3.1.2. If $M \neq 0$, then $\text{Ass}(M)$ is not empty. In fact, any ideal which is maximal in the set $\{\text{ann}(x) \mid x \in M, x \neq 0\}$ is prime.

If R is Noetherian and $M \neq 0$, then $\text{Ass}(M) \neq \emptyset$.

Proposition 3.1.3. $P \in \text{Ass}(M)$ iff there exists an injective map of R -modules $R/P \rightarrow M$.

Proposition 3.1.4. Suppose R is Noetherian and M finitely generated R -module. Then there exists a filtration

$$0 = M_0 \subseteq M_1 \subseteq \dots \subseteq M_k = M$$

such that the subquotients $gr^i(M) = M_i/M_{i-1}$ are isomorphic to R/P_i where P_i are prime.

Proposition 3.1.5. Suppose M is an R -module and $N \subseteq M$ is a submodule. Then

$$\text{Ass}(N) \subseteq \text{Ass}(M) \subseteq \text{Ass}(N) \cup \text{Ass}(M/N).$$

Proof. First containment.

$$P \in \text{Ass}(N) \implies P = \text{ann}(x) \quad x \in N \subseteq M \implies P \in \text{Ass}(M).$$

Second containment.

Take $P \in \text{Ass}(M)$, then $P = \text{ann}(y)$ where $y \in M$. Consider $\bar{y} \in M/N$.

First case is that $\text{ann}(\bar{y}) = P$, then $P \in \text{Ass}(M/N)$.

Second is that $\text{ann}(\bar{y}) > \text{ann}(y) = P$. Then there exists $s \in R$ such that $s \in \text{ann}(\bar{y})$ but $s \notin P$. Then $sy \in M, s\bar{y} = s\bar{y} = 0 \in M/N$, which tells us that $sy \in N$.

We know that $r \in \text{ann}(sy) \iff rs \in \text{ann}(y)$. Note that $\text{ann}(sy) = P$. □

Example 3.1.6. Consider $\mathbb{C}[x, y]/(x^2, xy) = M$. Then

$$\text{Ass}_{\mathbb{C}[x, y]}(M) = \{(x), (x, y)\}.$$

We know this from observing $\text{ann}(y) = (x), \text{ann}(x) = (x, y)$.

3.2 Prime Avoidance

Theorem 3.2.1. Suppose I_1, I_2, \dots, I_n, J are ideals such that $J \subseteq \cup_{i=1}^n I_i$. If either

1. the ambient ring R contains an infinite field, or
2. at most two of the ideals I_1, I_2, \dots, I_n are not prime,

then $J \subseteq I_j$ for some j .

Proposition 3.2.2.

$$\bigcup_{P \in \text{Ass}(M)} P = \{0\} \cup \{x \in R \mid x \text{ is a zero-divisor on } M\}.$$

Proposition 3.2.3. Suppose M is a finitely generated module over a Noetherian ring R . Then $\text{Ass}(M)$ automatically contains any minimal elements in the set

$$\{P \subseteq R \mid P \text{ prime}, P \supseteq \text{ann}(M)\}.$$

Definition 3.2.4. An ideal $I \subseteq R$ is *primary* iff $|\text{Ass}(R/I)| = 1$. Specifically, say $\text{Ass}(R/I) = \{P\}$, then we say I is P -primary.

Proposition 3.2.5. An ideal I is P -primary iff

1. Every element $x \notin P$ is not a zero divisor in R/I .
2. Every element $x \in P$ has a power $x^n \in I$.

Proposition 3.2.6. An ideal $I \subseteq R$ is P -primary iff any of the following criteria are true.

1. If $xy \in I$, and $x \notin P$, then $y \in I$.

Proposition 3.2.7. An ideal $I \subseteq R$ is primary iff

1. if $xy \in I$ and $x \notin I$, then $y^n \in I$ for some $n > 0$.
2. if $xy \in I$, $x \notin I, y \notin I$, then $x^n \in I$ and $y^m \in I$ for some $n, m > 0$.

Proposition 3.2.8. In a Noetherian ring R , every ideal is a finite intersection of irreducible ideals.

The above could be proven by looking at the maximal counterexample.

Proposition 3.2.9. If $I \subseteq R$ is an irreducible ideal, then I is primary.

Combine them together we have the following.

Proposition 3.2.10. Any ideal of R is a finite intersection of primary ideals.

Note that we proved irreducible implies primary, but the converse is false.

Also we showed that if I is P -primary, then $P^n \subseteq I \subseteq P$. The converse is not true either.

Proposition 3.2.11. *If M is maximal and $M^n \subseteq I \subseteq M$, then I is M -primary.*

Minimal primes in the primary decomposition are unique.

If R is a UFD, so is $R[x]$. How do we check whether a polynomial $P = a_0 + a_1x + \cdots + a_nx^n$ is irreducible?

1. $\gcd(a_0, \dots, a_n) = 1$
2. P is irreducible in $Q[x]$ where Q is the fraction field.

If M is an R -module. (R Noetherian, M finitely generated).

Definition 3.2.12. A submodule $N \subseteq M$ is *P -primary* in M if $\text{Ass}_R(M/N) = \{P\}$.

3.3 Nakayama's Lemma

Proposition 3.3.1. *Suppose R is a ring, M a finitely generated module over R , $I \subseteq R$ an ideal. If $IM = M$, then there exists $a \in R$ such that $a \equiv 1 \pmod I$ and $aM = 0$.*

Definition 3.3.2. The *Jacobson radical* of a ring R is the intersection of all maximal ideals of R , called the *Jacobson radical*.

Proposition 3.3.3 (Nakayama's lemma). *$x \in R$ is an element of the Jacobson radical iff $1 + rx$ is a unit for any $r \in R$.*

Proposition 3.3.4 (Nakayama's Lemma). *If N is a finitely generated R -module and $mN = N$ then $N = 0$.*

local rings have unique maximal ideal.

Nakayama's lemma has other different forms, for example the following.

Theorem 3.3.5. *Suppose R is a local ring, M is a finitely generated R -module, $x_1, \dots, x_n \in M$ are generators of M mod the maximal ideal, then x_1, \dots, x_n generate M .*

If you throw out "finitely generated", the above theorem is false.

Definition 3.3.6. An *idempotent* in R is an element $e \in R$, $e^2 = e$.

Proposition 3.3.7. *If $e \in R$ is idempotent, then $R \cong R/(e) \times R/(1 - e)$.*

Proposition 3.3.8. *If R is a ring, $I \subseteq R$ a finitely generated ideal satisfying $I^2 = I$, then there exists an idempotent $e \in R$ s.t. $(e) = I$. (implies $R \cong S \times I$).*

Proposition 3.3.9 (Cayley Hamilton Theorem). *Suppose M is a module over a ring R that can be generated by n elements, and $\phi : M \rightarrow M$ is a module homomorphism $\phi(M) \subseteq IM$, then there exists a polynomial*

$$f(x) = x^n + a_1x^{n-1} + \cdots + a_n, \quad a_j \in I^j.$$

such that for all $m \in M$,

$$0 = \phi^n m + a_1 \phi^{n-1} m + \cdots + a_n m.$$

Definition 3.3.10. Suppose R is a ring and S is an *R -algebra* (there's a ring homomorphism ϕ from R to S). An element $s \in S$ is *integral over R* if there exists a monic polynomial $p(x) = x^n + a_1 x^{n-1} + \cdots + a_n \in R[x]$ such that $p(s) = 0$, which means

$$s^n + \phi(a_1)s^{n-1} + \cdots + \phi(a_n) = 0.$$

Recall

Theorem 3.3.11 (Rational zeros theorem). *If*

$$x^n + a_1 x^{n-1} + \cdots + a_n$$

is a polynomial with integer coefficients and $p/q \in \mathbb{Q}$, then $p/q \in \mathbb{Z}$.

SEARCH

Remark that if $\text{Im}(\phi)$ is a subring of S , then s is integral over R iff s is integral over $\text{Im}(\phi)$.

WLOG we often assume $R \subseteq S$ when discussing integrality.

Definition 3.3.12. For $R \subseteq S$ a subring, define \overline{R} , the *integral closure of R* , to be

$$\{s \in S \mid s \text{ is integral over } R\}.$$

Theorem 3.3.13. \overline{R} is a ring containing R .

Proof. To show $R \subseteq \overline{R}$, we know $r \in R$ satisfies $x - r$. □

Definition 3.3.14. If $R \subseteq S$ and $s \in S$, we define

$$R[s] := \text{subring of } S \text{ generated by } R \text{ and } s = \left\{ \sum_i^r a_i s^i \mid a_i \in R \right\}.$$

Proposition 3.3.15. *TFAE*

1. s is an integral over R
2. The set $R[s] \subseteq S$ is a finitely-generated R -module
3. there exists a subring $R \subseteq T \subseteq S$ s.t. T is a finitely generated R -module and $s \in T$.

Proof. 2 \implies 3 is immediate when $T = R[s]$.

3 \implies 1 uses Cayley-Hamilton Theorem. □

In geometry, we are taking out singularities by taking integral closures.

Proposition 3.3.16. *If R is a UFD, then R is integrally closed in its field of fractions K .*

Proof. Suppose $\frac{r}{s} \in K$, $\gcd(r, s) = 1$, and $\frac{r}{s}$ is integral over R . We multiply $f(\frac{r}{s})$ by s^n , then

$$0 = r^n + a_1 s^{n-1} + \cdots + a_n s^n \implies r^n = s(-a_1 r^{n-1} - \cdots - a_n s^{n-1}).$$

This means s divides r but $\gcd(r, s) = 1$. Thus it has to be s is a unit in R . Thus $rs^{-1} \in R$. \square

Proposition 3.3.17. *Suppose $R \subseteq S$ is a subring, $U \subseteq R$ is a multiplicatively closed subset.*

$$\overline{R}^S[U^{-1}] = \overline{R[U^{-1}]}^{S[U^{-1}]}.$$

Proof. 1. If $\frac{r}{s} \in \overline{R}[U^{-1}]$, then $\frac{r}{s}$ is integral over $R[U^{-1}]$. Since $\frac{r}{s} \in \overline{R}[U^{-1}]$, we know $r \in \overline{R}$. \square

Definition 3.3.18. Suppose $R \subseteq S$. We say that this inclusion satisfies

1. *lying over* if for any prime $p \in R$, there exists a prime $q \in S$ such that $p = R \cap q$.
2. *going up* if for any inclusion of primes $p_0 \subseteq p_1$ of R , and prime q_0 of S s.t. $q_0 \cap R = p_0$, there exists q_1 of S s.t. $q_0 \subseteq q_1$ and $q_1 \cap R = p_1$.
3. *going down*: for any inclusion of primes $p_0 \supseteq p_1$ of R and q_0 in S with $q_0 \cap R = p_0$, there exists prime $q_1 \in S$ s.t. $q_0 \supseteq q_1$ and $q_1 \cap R = p_1$.

Example 3.3.19. Consider $\mathbb{Z} \subseteq \mathbb{Q}$. *lying over* No, *going up* No, *going down* Yes.

Example 3.3.20. Consider $\mathbb{C}[x] \subseteq \mathbb{C}[x, y]$. The only prime ideal of $\mathbb{C}[x]$ is $x - \alpha$ where $\alpha \in \mathbb{C}$.

lying over Yes, *going up*

Show that if $R \subseteq S$ is an *integral extension* $S = \overline{R}$, then some of these properties are automatically satisfied.

Proposition 3.3.21. *Suppose $R \subseteq S$ and S is integral over R . Then*

1. *This satisfies lying over*
2. *This satisfies going up*

Trick: we are going to use certain quotients and localizations to reduce this to an easiest case.

Proof. Say we want to prove going up.

Suppose we have prime of S , q_0 , and primes of R , $p_0 \subseteq p_1$, and $p_0 = q_0 \cap R$. Then define

$$R' = R/p_0 \quad S' = S/q_0.$$

There is a map from $R' \rightarrow S'$. (check it's well-defined). (omitted)

Moreover, if S is integral over R , then S' is integral over R' . \square

Proof. Say $P \subseteq R$ is a prime ideal.

Define $U = R - P$, consider

$$R_P = R[U^{-1}] \subseteq S[U^{-1}] = S_P.$$

The idea is to find a prime ideal Q of S_P that contains $P[U^{-1}]$. If we can do that, then $q = Q \cap S$ is a prime of S that doesn't contain any elements of $U = R - P$, which is equivalent to saying that $q \cap R \subseteq P$. And $q = Q \cap S \supseteq P$ and so $q \cap R \supseteq P$.

So this reduces us to the case $R \subseteq S$, R is local, and we want to find an ideal of S that is prime and contains the maximal $m \subseteq R$.

Idea:

There is an ideal of S , which is mS , m the maximal in R . If we can find a maximal ideal of S containing mS , then it's prime and contains m . This is impossible iff $mS = S$.

From Nakayama's lemma, if S was finitely generated, we are done. However we don't know that.

If $mS = S$, then $\sum a_i x_i = 1$, where $a_i \in m$ and $x_i \in S$. Let $T_c S$ be the subring of S generated by $x_1 \cdots x_n$, as $T = R[x_1 \cdots x_n]$.

The claim is that T is a finitely-generated R -module and $mT = T$. Now we could use Nakayama's lemma, to get a contradiction saying that $T = 0$. \square

Example 3.3.22. We show $R \rightarrow S$ which is integral but not finitely generated. Consider $\mathbb{Q} \subseteq \overline{\mathbb{Q}} \subseteq \mathbb{C}$. Note that $\overline{\mathbb{Q}}$ is not finitely generated.

3.4 Nullstellensatz

If $I \subseteq \mathbb{C}[x_1 \cdots x_n]$ ideal, then $I(V(I)) = \sqrt{I}$.

Proposition 3.4.1. Suppose R, S are domains K the fraction field of R , and that the fraction field of S , L , is integral over K . Then any prime ideal $P \subseteq S$ is either 0 or it has nontrivial intersection with R .

Proof. P is a prime ideal of S that's not trivial, which implies that P contains some nonzero element, denoted by b . Since $b \in S$, the image $b/1 \in L$ is integral over K . Thus there exist elements

$$\frac{a_1}{u_1}, \frac{a_2}{u_2}, \dots, \frac{a_n}{u_n}$$

such that

$$0 = b^n + \frac{a_1}{u_1}b^{n-1} + \cdots + \frac{a_n}{b_n} \in L.$$

Then we could have $\frac{a_n}{b_n} = -b$ times something in L . Multiply by some large element to clear all denominators $u_1 u_2 \cdots u_n$.

Then

$$(u_1 u_2 \cdots u_n) a_n = -b \text{ something in } S \in P.$$

Since the LHS is in R , if LHS $\neq 0$, we are done.

Since R was a domain and u_i 's were in denominators, we could only have $a_n = 0$. Then the original polynomial will be

$$0 = b^n + \cdots + \frac{a_{n-1}}{u_{n-1}}b.$$

Since $b \neq 0$ by assumption and S is a domain, we could divide both sides by b and just do so iteratively.

Therefore, every prime ideal of S intersects R nontrivially. \square

Corollary 3.4.2. *If S is integral over R , and $q_0 \subsetneq q_1$ proper containment of prime ideals, then*

$$q_0 \cap R \subsetneq q_1 \cap R$$

still proper.

The idea behind this is that integrality preserves dimensions.

Proof. Define $p_0 = q_0 \cap R, p_1 = q_1 \cap R$, we know $p_0 \subseteq p_1$. We still get an injective map

$$R/p_0 \rightarrow S/q_0.$$

We each have ideals p_1/p_0 and q_1/q_0 , this map also preserves integrality. The fact that q_1 properly contains q_0 implies that $q_1/q_0 \neq (0)$. Since $R/p_0 \subseteq S/q_0$ are domains since they are moded out by prime ideals.

Then

$$\begin{aligned} R/p_0 \cap q_1/q_0 &= (R/R \cap q_0) \cap (q_1/q_0) \\ &= (R \cap q_1)/R \cap q_0 \\ &= (R \cap q_1) \neq R \cap q_0, \end{aligned}$$

as desired. \square

Proposition 3.4.3. *Suppose $R \subseteq S$ and S is integral over R . Then S is a field iff R is a field. (Also S needs to be an integral domain).*

Proof. Suppose R is a field, $x \in S$. Since S is integral over R , we have

$$0 = x^n + a_1 x^{n-1} + \cdots + a_n, \quad a_i \in \mathbb{R}.$$

We claim that WLOG we can assume $a_n \neq 0$ because S is an integral domain. Because R is a field, a_n has an inverse.

$$a_n = x(-x^{n-1} - a_1x^{n-2} - \dots - a_{n-1})$$

$$1 = x \left(\frac{-x^{n-1} - a_1x^{n-2} - \dots - a_{n-1}}{a_n} \right)$$

Thus x is a unit, which implies S is a field.

Other direction: Suppose S is a field. If R is not a field, then there exists some nontrivial maximal ideal of R : $(0) \subsetneq m$. By going up we get $(0) \subseteq P$, and $P \cap R = m$, which implies $P = (0)$. \square

Nullstellensatz

1. maximal ideals of $\mathbb{C}[x_1, \dots, x_n]$ are of the form $(x_1 - a_1, \dots, x_n - a_n)$ where $a_i \in \mathbb{C}$.
2. For any ideal J , $I(V(J)) = \sqrt{J}$.

where $V(J)$ consists of all n -tuples $x = (x_1, \dots, x_n) \in \mathbb{C}^n$ such that $f(x) = 0$ for all $f \in J$, and $I(U)$ is the ideal of all polynomials that vanish on the set U . Also \sqrt{J} denotes the radical of J , which means all $r \in \mathbb{C}[x_1, \dots, x_n]$ such that $r^n \in J$ for some $n \in \mathbb{Z}^+$.

Definition 3.4.4. A *Jacobson ring* is a ring R satisfying: any prime ideal P is an intersection of maximal ideals

$$P = \bigcap_{\alpha \in A} m_\alpha.$$

Example 3.4.5. \mathbb{Z} is a Jacobson ring. Most prime ideals are already maximal ideals so it's the intersection of itself. The only left is (0) , which is the intersection of all prime ideals in \mathbb{Z} .

Remark that if P is not maximal, this intersection has to be infinite because otherwise it violates prime decomposition thing.

Example 3.4.6. Local rings are typically not Jacobson rings. If we take $\mathbb{Z}_{(2)}$, we only have 2 prime ideals (0) and (2) , and (0) fails to be the intersection of maximal ideals.

The idea is that local rings are sort of “too small” to be Jacobson rings.

Example 3.4.7. Fields are Jacobson rings. (0) is the only ideal.

Theorem 3.4.8 (Nullstellensatz). Suppose R is a Jacobson ring and S is a finitely-generated R -algebra. In other words there is a surjection from $R[x_1, \dots, x_n]$ to S . Then

1. S is also a Jacobson ring
2. If η is any maximal ideal of S , then $m = R \cap \eta$ is a maximal ideal of R , and the map

$$R/m \rightarrow S/\eta$$

is a finite field extension. In other words, S/η is a finite dimensional module over R/m .

Suppose R is an algebraically closed field (\mathbb{C}). Then R is a Jacobson ring. Note that $\mathbb{C}[x_1, \dots, x_n]$ is a finitely generated algebra over \mathbb{C} .

Then Nullstellensatz tells us that

1. Every prime ideal $P \subseteq \mathbb{C}[x_1, \dots, x_n]$ is an intersection of maximal ideals.
2. If $\eta \subseteq \mathbb{C}[x_1, \dots, x_n]$ is maximal, then $\eta \cap \mathbb{C} = (0)$, and the map

$$\mathbb{C} \rightarrow \mathbb{C}[x_1, \dots, x_n]/\eta$$

is a finite field extension. Then, $\mathbb{C}[x_1, \dots, x_n]/\eta \cong \mathbb{C}$. There exists $(a_1, \dots, a_n) \in \mathbb{C}^n$ such that $(x_1 - a_1, x_2 - a_2, \dots, x_n - a_n) \subseteq \eta$, which is already maximal. Thus this is not only a containment but an equality.

If J is any ideal, then

$$\sqrt{J} = \{x \in \mathbb{C}[x_1, \dots, x_n] \mid x^n \in J \text{ some } n\} = \bigcap_{J \subseteq P} P.$$

If every prime is an intersection of maximal ideals, then

$$\bigcap_{J \subseteq P} P = \bigcap_{J \subseteq P} \bigcap_{P \subseteq m} m = \bigcap_{J \subseteq m} m,$$

where P prime and m maximal. We could rewrite the maximal ideals as

$$\begin{aligned} &= \bigcap_{J \subseteq (x_1 - a_1, \dots, x_n - a_n)} \{f \in \mathbb{C}[x_1, \dots, x_n] \mid f(a_1, \dots, a_n) = 0\} \\ &= \{f \in \mathbb{C}[x_1, \dots, x_n] \mid f(a_1, \dots, a_n) = 0 \text{ for all } (a_1, \dots, a_n) \in V(J)\} \end{aligned}$$

What do we know about $\mathbb{R}[x_1, \dots, x_n]$? Take $\eta \in \mathbb{R}[x_1, \dots, x_n]$. We have finite field extensions

$$\mathbb{R} \rightarrow \mathbb{R}[x_1, \dots, x_n]/\eta \cong \mathbb{C} \text{ or } \mathbb{R}.$$

Then we could play the same argument which tells us that the maximal ideal looks like $(x_1 - a_1, \dots, x_n - a_n)$ where $a_i \in \mathbb{R}$.

Is \mathbb{C} tells us that for some i , we have $x_i \mapsto \mathbb{C} - \mathbb{R}$, which gives us $x_i^2 - ax_i - b$. For any $j \neq i$, we have j goes to some complex number, which is equal to $r_j + s_j x_i$. Thus

$$\eta = (x_i^2 - ax_i - b, r_1 + s_1 x_i - x_1, r_2 + s_2 x_i - x_2, \dots, r_n + s_n x_i - x_n) = \mathbb{C}^n.$$

Every maximal ideal of $\mathbb{R}[x_1, \dots, x_n]$ is of one of the forms

1. $(x_1 - a_1, \dots, x_n - a_n)$ where $a_i \in \mathbb{C}$
2. or it corresponds to a pair of complex conjugate points

$$(a_1, \dots, a_n), (\overline{a_1}, \dots, \overline{a_n}) \in \mathbb{C}^n.$$

Then in 1 variable: $\mathbb{R}[x]$ have $(x - a)$ or $(x^2 + bx + c)$ where $b^2 - 4c < 0$ are the maximal ideals.
